

A Audit protocol, applied in this order to any cross-cohort benchmark

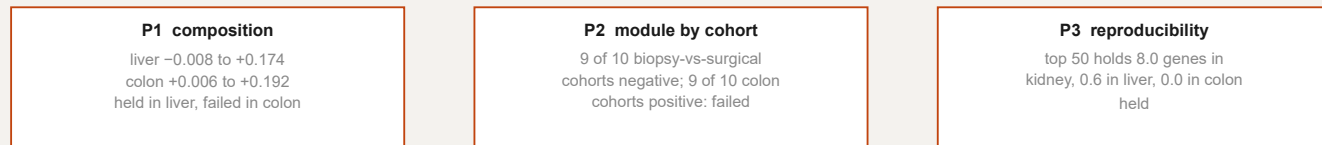

output: reporting checklist (Table 4)

B Development case: diabetic kidney disease (7 cohorts, 5 discovery)

C Application test: liver and colon, predictions hash-fixed before the data were read

D Where the findings apply, and where they do not

instability went with low cross-cohort effect concordance (p 0.66 colon, 0.22 kidney, 0.15 liver), not with cohort size

the module also rises with inflammation, so correcting on it is tissue-conditional; a control by the same procedure is preferred where available

three tissues, one disease per tissue; digests are local, so they fix the files, not an external date; no new biomarker is claimed
